

# Battery power plummets

## Overview

Just like the battery in your smartphone or laptop, the batteries in electric cars rely on controlled chemical reactions to store and release electricity – and, like all chemical reactions, they're sensitive to temperature. Get an EV battery outside its optimum operating temperature, and it'll be less efficient and run out of charge. Cold weather typically brings additional demands on a car's systems: in a wintry snap most drivers will turn the cabin temperature up, activate demisting and switch on heated seats and steering wheels, where fitted – all. Our experience suggests that extremely cold weather will typically trim somewhere between a fifth and a third off the range of your EV – and sometimes significantly more. It affects every electric vehicle, but some seem better able to. Yes, but that's not the really interesting news. What you're probably better focusing on is how some other, more familiar car makers fared – which is to say, rather badly. For instance, The Mercedes EQE 300 and Skoda. This is a topic the Norwegian Automobile Federation (NAF) is particularly interested in. Norway has moved faster into EVs than any other country – and since it suffers extreme winter weather, motoring organisations test electric.

How do I charge power storage? : r/SatisfactoryGame

The point of the power storage is to store excess power in a circuit and a battery on its own is not a circuit, so that might be why. Try connecting a machine to your biomass burner and have it draw energy. If there is excess energy still, then that should go to storage. Again, not certain.
