

How capacitors move charge

Overview

Take two electrical conductors (things that let electricity flow through them) and separate them with an insulator (a material that doesn't let electricity flow very well) and you make a capacitor: something that can store electrical energy. Adding electrical energy to a capacitor is called charging; releasing the energy from. The amount of electrical energy a capacitor can store depends on its capacitance. The capacitance of a capacitor is a bit like the size of a capacitor is measured in units called farads (F), named for English electrical pioneer Michael Faraday (1791–1867). One farad is a huge amount of capacitance, so, in practice, most of the capacitors we come across are much smaller. If you find capacitors mysterious and weird, and they don't really make sense to you, try thinking about gravity instead. Suppose you're standing at the bottom of some steps and you

How exactly is a capacitor charged? : r/AskPhysics

The net charge on a capacitor with unpolarized dielectric medium will always be zero, charged or not. It's the work that you(r battery/emf) do(es) in moving the charges which is stored in capacitor: the more you work to separate the charges, the greater the field energy density in your capacitor.

Eli5: How does a capacitor work? : r/explainlikeimfive

You charge up a capacitor by putting a potential difference across either side, effectively dragging electrons (or charge) from one side of the gap, pushing it around the circuit to the other side of the gap, stuffing a bunch of electrons together. ... How do capacitors get charged?

When a capacitor is connected between the terminals of a power supply (or cell) electrons are forced off of one of the capacitor's plates and forced onto the opposite plate through the power supply. Due to the action of the power supply which causes a current to flow electrons are forced off of the positive plate (hence there is a deficiency of negative charge and it gains ...

eli5: I understand how capacitors store electrical energy, but how ...

Yes, the charges move around the circuit from one plate to the other, that's how the current is generated. The charges *really* want to get to the other plate because of the voltage difference. The shortest distance is to just jump straight to the other plate but the dielectric prevents that, so the only path left to get to the other plate is to run through the circuit.

Do capacitors allow electrons to go through it while holding some charge?

Electrons flowing is an electric current. A current of one ampere is, by definition, a flow of one coulomb of electric charge per second. The charge of one electron is 1.6×10^{-19} coulomb, which means one ampere is 6250000 trillion electrons per second. When a capacitor is charged, no electrons go through the dielectric.

\$begingroup\$ Since the circuit is at a constant potential difference and the pulling apart of the capacitor plates reduces the capacitance, the energy stored in the capacitor also decreases.
